Answer to Question 1:

Binary search works by dividing a sorted array in half repeatedly until the target element is found. Best case time complexity is O(1) if the target is in the middle. The average and worst-case time complexity is O(log n).

Pseudocode:

```
def binary_search(arr, target):
  low = 0
  high = len(arr) - 1
  while low <= high:
    mid = (low + high) // 2
    if arr[mid] == target:
      return mid
    elif arr[mid] < target:
      low = mid + 1
    else:
      high = mid - 1
  return -1
```

Answer to Question 2:

Arrays have contiguous memory while linked lists use discrete nodes connected by pointers. Arrays have O(1) access time but O(n) insertion/deletion. Linked lists have O(n) access time but O(1) insertion/deletion if the node is known.
